# **Acronyms in This Document**

A list of acronyms used in this document.

Acronym	Definition
AP	Application Processor
DSI	Display Serial Interface
CSI-2	Camera Serial Interface 2
DDR	Double Data Rate
FV	Frame Valid
GPLL	General Purpose PLL
НВР	Horizontal Back Porch
HFP	Horizontal Front Porch
HS	High Speed
I2C	Inter-Integrated Circuit
LP	Low Power
LV	Line Valid
LVDS	Low Voltage Differential Signal
MIPI	Mobile Industry Processor Interface
OpenLDI	Open LVDS Display Interface
PLL	Phase Locked Loop
RD	Reference Design
RX	Receiver
TX	Transmitter
VBP	Vertical Back Porch
VFP	Vertical Front Porch
VCO	Voltage Controlled Oscillator

# 1. Introduction

Mobile Industry Processor Interface (MIPI®) Display Serial Interface (DSI) is one of the most popular display interface in the consumer market today. On the other hand, Open LVDS Display Interface (OpenLDI) low voltage differential signal (LVDS) is still popular in some areas as the main predecessor of display interface. The majority of image sensors and application processors (AP) in the consumer market use MIPI Camera Serial Interface 2 (CSI-2) as a video signal interface. In some cases, the interface and/or format conversion is useful to connect devices which cannot connect directly.

The Lattice Semiconductor MIPI DSI/CSI-2 to OpenLDI LVDS Interface Bridge reference design for CrossLink™-NX devices takes DSI or CSI-2 MIPI data and converts the data to OpenLDI format on LVDS. The MIPI RX module can also be realized by a MIPI Hardened macro IP or soft macro utilizing general DDR modules (D-PHY Soft IP) while LVDS TX module is realized by soft macro utilizing general DDR modules.

The reference design is available on the MIPI DSI/CSI-2 to OpenLDI LVDS Interface Bridge web page.

#### 1.1. Features

- Single DSI input (RGB888) to single or dual channel LVDS outputs (RGB888).
- Single CSI-2 input (RGB888, RAW8, RAW10, RAW12, RAW14) to single or dual channel LVDS outputs (RGB888).
- RX channel can have one, two, or four lanes with the bandwidth up to 1.5 Gbps per lane using RX D-PHY Soft IP. The bandwidth can be up to 2.5 Gbps per lane when the RX Hardened D-PHY IP is used.
- Number of TX data lanes is four (RGB888) per TX channel.
- Maximum TX bandwidth is 945 Mbps per lane.
- Image cropping option is available in case of CSI-2 input.
- Dynamic parameter setting is possible via inter-integrated circuit (I2C) in case of CSI-2 input.

# 1.2. Block Diagram

Figure 1.1 shows the block level diagram of the MIPI DSI/CSI-2 to OpenLDI LVDS Interface Bridge reference design with single TX channel.

There exist two main clock domains for main video data path: byte clock and pixel clock. GPLL is required to generate the edge clock of LVDS TX module. Also, it can be used to generate the continuous byte clock when RX D-PHY is in HS\_LP mode. I2C target modules enables parameter change on the fly if necessary for CSI-2 RX.

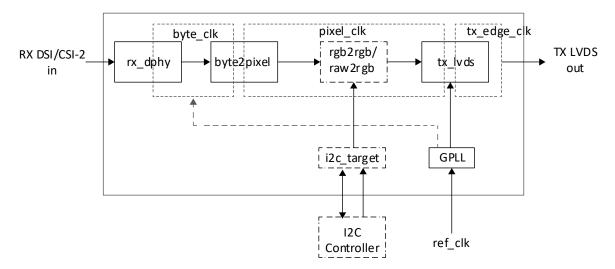

Figure 1.1. DSI/CSI-2 to OpenLDI LVDS Interface Bridge Block Diagram

#### 1.3. RX and TX Permutations

Table 1.1 shows the available permutations of RX and TX configurations. Some permutations exist only for DSI and some only for CSI-2 due to the limitations of the Byte-to-Pixel IP used in this reference design. Note that TX Data Type is the same as the RX Data Type in the case of DSI. The TX Data Type is always RGB888 in the case of CSI-2.

Table 1.1. RX and TX Permutation

D-PHY Type	Data Type	Number of RX Lanes	RX Gear	Number of Pixels/ Pixel Clock	TX Gear	Number of TX Channel	
		1	8	1	7	1	
		1	16	1	7	1	
DCI	DCD000	2	8	1	7	1	
DSI	RGB888	2	16	1	7	1	
		4	8	1	7	1	
		4	4 8	2	7	2	
	1 RGB888, RAW8, RAW10, RAW12 2		1	8	1	7	1
		16	1	7	1		
		2	8	2	7	2	
		NAVIO, NAVIZ	2	16	1	7	1
CSI-2		4	8	1	7	1	
		1	8	1	7	1	
DANA 4	2	8	1	7	1		
	RAW14	4	0	2	_	1	
			8	2	7	2	

The Microsoft Excel sheet (mipi2lvds\_clock.xlsx) is provided to get the byte clock, TX edge clock, and others from RX bandwidth, in addition to other information. This sheet is useful in configuring IPs. A sample entry is shown in Figure 1.2. By entering MIPI bandwidth and other information, Byte clock, LVDS bandwidth, and TX ECLK are automatically calculated. The results can be used to configure TX LVDS IP and GPLL.

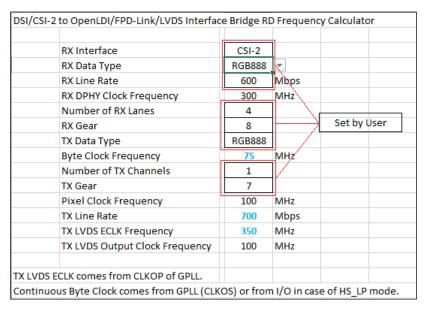

Figure 1.2. Bandwidth and Clock Frequency Calculator

# 2. Parameters and Port List

There are two directive files for this reference design:

- synthesis\_directives.v used for design compilation by Lattice Radiant™ software and for simulation.
- simulation\_directives.v used for simulation.

You can modify these directives according to your own configuration. The settings in these files must match RX D-PHY IP, Byte-to-Pixel IP, and TX LVDS IP settings created in Lattice Radiant.

## 2.1. Synthesis Directives

Table 2.1 shows the synthesis directives that affect this reference design. These are used for both synthesis and simulation. As shown in Table 2.1 and Table 2.2, some parameter selections are restricted by other parameter settings.

**Table 2.1 Synthesis Directives** 

Category	Directive	Remarks	
External reference clock <sup>1</sup>	EXT_REF_CLK	Enable this when the reference clock is fed from a pin.	
RX D-PHY Type	RX_TYPE_DSI	Define the D-PHY type on the RX channel. Only one of these	
	RX_TYPE_CSI2	directives must be defined.	
RX Data Type	RX_RGB888	Define the data type on the RX channel. Only one of these	
	RX_RAW8	directives must be defined. In case of DSI, only RGB888 is allowed.	
	RX_RAW10	In case of CSI-2, only RGB888, RAW8, RAW10, RAW12, and RAW14 are allowed.	
	RX_RAW12	are allowed.	
	RX_RAW14		
Number of RX Channel	NUM_RX_LANE_1	Number of lanes in the RX channel. Only one of these three	
Lanes	NUM_RX_LANE_2	directives must be defined.	
	NUM_RX_LANE_4		
RX D-PHY Clock Gear	RX_GEAR_8	Number of RX clock gears on the RX channel. Only one of these	
	RX_GEAR_16	directives must be defined.	
RX Hardened D-PHY	RX_DPHY_HARD	Enable this to use Hardened D-PHY. If undefined, Soft D-PHY is used.	
RX D-PHY Clock Mode <sup>2</sup>	RX_CLK_MODE_HS_ONLY	RX D-PHY clock mode. Only one of these two directives must be	
	RX_CLK_MODE_HS_LP	defined.	
Line Buffer Depth	LB_DEPTH_512	Define the depth of the line buffer in case the RX Data Type is	
	LB_DEPTH_1024	RAW8, RAW10, RAW12, or RAW14. This depth must be equal or	
	LB_DEPTH_2048	greater than the active pixel count per line, irrespective of the data	
	LB_DEPTH_4096	- type.	
Sync Signal Polarity	SYNC_POLARITY_POS	Define sync signal (VSYNC, HSYNC) polarity. Only one of these two	
	SYNC_POLARITY_NEG	directives must be defined.	
Data Enable Polarity	DE_POLARITY_POS	Define data enable (DE) polarity. Only one of these two directives	
	DE_POLARITY_NEG	must be defined.	
TX Data Type <sup>3</sup>	TX_RGB888	Define the data type on TX channel. Only RGB888 must be defined in all cases. (User must not modify this)	
Number of TX Channels	NUM_TX_CH_1	Number of channels on TX. Only one of these two directives must	
	NUM_TX_CH_2	be defined.	
TX LVDS Gear	TX_GEAR_7	Number of TX clock gears on RX channel. Only TX_GEAR_7 is used. (User must not modify this)	
Parameter set by I2C	USE_I2C	Define this to use I2C I/F to set the parameters on the fly. This is applicable to CSI-2 input only.	

Category	Directive	Remarks	
Software Reset Register <sup>4</sup>	SW_RST_N {value}	Default value of the software reset register of I2C Target module.  Value must be 1'b0 or 1'b1 Applicable only when USE_I2C is defined. Active low.	
Shift Register Delay <sup>5</sup>	SR_DELAY {value}	Define shift register delay. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 8'd2 – 8'd255. Applicable only to CSI-2 input with RGB888.	
Bayer Pattern <sup>6</sup>	BAYER_PATTERN {value}	Define the Bayer pattern. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 2'b00 – 2'b11. Applicable only to CSI-2 input with RAW8/RAW10/RAW12/RAW14.	
Horizontal Front Porch <sup>7</sup>	HFP {value}	Define the horizontal front porch. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 8'd1 – 8'd255. Applicable only to CSI-2 input.	
HSYNC Pulse Length <sup>7</sup>	HS_LENGTH {value}	Define HSYNC pulse length. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 8'd1 – 8'd255. Applicable only to CSI-2 input.	
Vertical Front Porch <sup>8</sup>	VFP {value}	Define the vertical front porch. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 6'd1 – 6'd63. Applicable only to CSI-2 input.	
VSYNC Pulse Length <sup>8</sup>	VS_LENGTH {value}	Define VSYNC pulse length. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 6'd1 – 6'd63. Applicable only to CSI-2 input.	
Left Pixel Trimming <sup>9</sup>	LEFT_TRIM {value}	Define the number of pixels to be trimmed before TX. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 6'd0 – 6'd63. Applicable only to CSI-2 input.	
Horizontal Active Pixels on TX <sup>9</sup>	H_TX_PEL {value}	Define the number of active pixels to send on TX. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 12'd1 – 12'd4095. The value must be even in case of NUM_TX_CH_2. Applicable only to CSI-2 input.	
Top Line Trimming <sup>10</sup>	TOP_TRIM {value}	Define the number of lines to be trimmed before TX. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 6'd0 – 6'd63. Applicable only to CSI-2 input.	
Vertical Active Lines on TX <sup>10</sup>	V_TX_LINE {value}	Define the number of active lines to be sent on TX. This value is used as a fixed value when USE_I2C is not defined and used as the default value of the I2C register when USE_I2C is defined. Value must be 12'd1 – 12'd4095. Applicable only to CSI-2 input.	

#### Notes:

- 1. The external clock is required in most cases since the clock ratio between RX side and TX side is usually not simple.
- 2. HS\_LP mode means non-continuous clock mode and HS\_ONLY means continuous clock mode. HS\_LP mode works only if RX byte clock can be generated internally or directly fed from I/O pin.
- 3. TX data type must match RX data type in case of RGB input. RGB888 output is used for all RAW input.
- 4. Logical OR between this register and system reset (reset\_n\_i) is used to reset modules other than I2C target module.
- 5. Refer to the Sync Signal Generation section for details.
- 6. Refer to the RGB Data Creation section for pattern details.
- 7. (HFP + HS\_LENGTH) must be less than the horizontal blanking period after the byte-to-pixel conversion. It is your responsibility to manage this. Small values are recommended if you have no idea about the length of the blanking period.

FPGA-RD-02216-1.1 9

© 2025 Lattice Semiconductor Corp. All Lattice trademarks, registered trademarks, patents, and disclaimers are as listed at www.latticesemi.com/legal.

- 8. (VFP + VS\_LENGTH) must be less than the vertical blanking period after the byte-to-pixel conversion. It is your responsibility to manage this. Small values are recommended if you have no idea about the length of the blanking period.
- 9. (LEFT\_TRIM + H\_TX\_PEL) cannot exceed the horizontal active pixel count of the incoming RX data. It is user's responsibility to manage this.
- 10. (TOP\_TRIM + V\_TX\_LINE) cannot exceed the vertical active line count of the incoming RX data. It is user's responsibility to manage this.

## 2.2. Simulation Directives

Table 2.2 shows the simulation directives for this reference design.

**Table 2.2. Simulation Directives** 

Category	Directive	Remarks	
Simulation setup	SIM	Define to select the right behavioral model in simulation.	
Reference clock period	REF_CLK {value}	Reference clock period in ps	
RX D-PHY clock period	DPHY_CLK {value}	RX DPHY clock period in ps	
Number of frames to run	NUM_FRAMES {value}	Number of video frames fed by testbench	
Number of active lines	NUM_LINES {value}	Number of active video lines per frame	
Number of active pixels	NUM_PIXELS {value}	Number of active video pixels per line	
HSYNC period in DSI	DSI_HSA_PAYLOAD {value}	HSYNC active count in the unit of payload byte. Applicable to DSI RX.	
Blanking period in DSI	DSI_BLLP_PAYLOAD {value}	Blanking period in the unit of payload byte. Used in HS_ONLY mode. Applicable to DSI RX.	
Horizontal Back Porch in DSI <sup>1</sup>	DSI_HBP_PAYLOAD {value}	Horizontal Back Porch or Low Power period in the unit of payload byte count. Used in HS_LP mode or non-burst sync pulse in HS_ONLY mode. Applicable to DSI RX.	
Horizontal Front Porch in DSI <sup>1</sup>	DSI_HFP_PAYLOAD {value}  Horizontal Front Porch or Low Power period in the payload byte count. Used in HS_LP mode or non-legal pulse in HS_ONLY mode. Applicable to DSI RX.		
VSYNC period in DSI	DSI_VSA_LINES {value}	Number of VSYNC active lines. Applicable to DSI RX.	
Vertical Back Porch in DSI	DSI_VBP_LINES {value}	Number of Vertical Back Porch lines. Applicable to DSI RX.	
Vertical Front Porch in DSI	DSI_VFP_LINES {value}	Number of Vertical Front Porch lines. Applicable to DSI RX.	
EOTP packet on/off in DSI	DSI_ETOP_ENABLE {value}	Enable/Disable EOTP (End of Transmission Packet). Applicable to DSI RX. Value must be 1 (enable) or 0 (disable).	
Blanking period in DSI	DSI_LPS_BLLP_DURATION {value}	Blanking (LP) period in ps. Used in HS_LP mode. Applicable to DSI RX.	
Horizontal Back Porch period in DSI <sup>1</sup>	DSI_LPS_HBP_DURATION {value}  Horizontal Back Porch period (using LP mode) in for non-burst sync events and burst mode in HS_Applicable to DSI RX.		
Horizontal Front Porch period in DSI <sup>1</sup>	DSI_LPS_HFP_DURATION {value}	Horizontal Front Porch period (using LP mode) in ps. Used for non-burst sync events and burst mode in HS_LP mode. Applicable to DSI RX.	
Initial delay on RX channel	READY_DURATION {value}	Initial delay to activate RX channel in ps.	
Line Gap period in CSI-2	DPHY_LPS_GAP {value}	Line Gap time in ps. Applicable to CSI-2 RX.	
Frame Gap period	FRAME_LPM_DELAY {value}	Frame Gap time in ps. This is LP period between Frame End and Frame Start in case of CSI-2 and LP period after VFP period end and before VSYNC start in case of DSI.	
Software Reset Register <sup>2</sup>	I2C_SW_RST_N {value}	Write value to the software reset register of I2C target module. Value must be 1'b0 or 1'b1. Applicable only when USE_I2C is defined. Active low.	
Shift Register Delay <sup>3</sup>	I2C_SR_DELAY {value}	Write value to the shift register delay register of I2C target. Value must be $8'd2 - 5'd255$ . Applicable only to CSI-2 input with RGB888.	

Category	Directive	Remarks
Bayer Pattern <sup>4</sup>	I2C_BAYER_PATTERN {value}	Write value to the Bayer pattern register of I2C target.  Value must be 2'b00 – 2'b11. Applicable only to CSI-2 input with RAW8/RAW10/RAW12/RAW14.
Horizontal Front Porch <sup>5</sup>	I2C_HFP {value}	Write value to the horizontal front porch register of I2C target. Value must be 8'd1 – 8'd255. Applicable only to CSI-2 input.
HSYNC Pulse Length <sup>5</sup>	I2C_HS_LENGTH {value}	Write value to HSYNC pulse length register of I2C target. Value must be 8'd1 – 8'd255. Applicable only to CSI-2 input.
Vertical Front Porch <sup>6</sup>	I2C_VFP {value}	Write value to the vertical front porch register of I2C target. Value must be 6'd1 – 6'd63. Applicable only to CSI-2 input.
VSYNC Pulse Length <sup>6</sup>	I2C_VS_LENGTH {value}	Write value to VSYNC pulse length register of I2C target. Value must be 6'd1 – 6'd63. Applicable only to CSI-2 input.
Left Pixel Trimming <sup>7</sup>	I2C_LEFT_TRIM {value}	Write Value to the pixel trim register of I2C target. Value must be 6'd0 – 6'd63. Applicable only to CSI-2 input.
Horizontal Active Pixels on TX <sup>7</sup>	I2C_H_TX_PEL {value}	Write value to the active pixel register of I2C target. Value must be 13'd1 – 13'd8191. The value must be even in case of TX_GEAR_14. Applicable only to CSI-2 input.
Top Line Trimming <sup>8</sup>	I2C_TOP_TRIM {value}	Write value to the line trim register of I2C target. Value must be 6'd0 – 6'd63. Applicable only to CSI-2 input.
Vertical Active Lines on TX <sup>8</sup>	I2C_V_TX_LINE {value}	Write value to the active line register of I2C. Value must be 12'd1 – 12'd4095. Applicable only to CSI-2 input.
DSI Mode	NON_BURST_SYNC_EVENTS BURST_MODE	Must match the setting in DSI Mode of Byte to Pixel IP. Both of this must be commented in case of Non Burst Sync Pulses setting of Byte to Pixel IP. Applicable only to DSI input
DSI Blanking Format	LP_BLANKING	Define to make Data Lanes goes into Low Power during Blanking Time

#### Notes:

- 1. Refer to MIPI® Alliance Specification for Display Serial Interface (DSI) Version 1.1 for details.
- 2. Logical OR between this register and system reset (reset\_n\_i) is used to reset modules other than I2C target module.
- 3. Refer to the Sync Signal Generation section for details.
- 4. Refer to the RGB Data Creation section for pattern details.
- 5. (I2C\_HFP + I2C\_HS\_LENGTH) must be less than the horizontal blanking period after the byte-to-pixel conversion. It is your responsibility to manage this. Small values are recommended if you have no idea about the length of the blanking period.
- 6. (I2C\_VFP + I2C\_VS\_LENGTH) must be less than the vertical blanking period after the byte-to-pixel conversion. It is your responsibility to manage this. Small values are recommended if you have no idea about the length of the blanking period.
- 7. (I2C\_LEFT\_TRIM + I2C\_H\_TX\_PEL) cannot exceed the horizontal active pixel count of the incoming RX data. It is your responsibility to manage this.
- 8. (I2C\_TOP\_TRIM + I2C\_V\_TX\_LINE) cannot exceed the vertical active line count of the incoming RX data. It is your responsibility to manage this.

# 2.3. Top-Level I/O

Table 2.3 shows the top level I/O of this reference design. Actual I/O depends on the customer's channel and lane configurations. All necessary I/O ports are automatically declared by compiler directives.

Table 2.3. DSI/CSI-2 to OpenLDI LVDS Interface Bridge Top Level I/O

Port Name	Direction	Description				
Clocks and Resets						
ref_clk_i	I	Input reference clock. Used to feed a clock to TX D-PHY PLL directly or indirectly. This port is declared only when EXT_REF_CLK is defined in synthesis_directives.v.				
reset_n_i	1	Asynchronous active low system reset				
Control Interf	ace (Optional	for CSI-2 RX)				
scl	I/O	I2C clock				
sda	1/0	I2C data				
DSI/CSI-2 RX I	nterface					
rx_clk_p_i	1	Positive differential RX D-PHY input clock				
rx_clk_n_i	1	Negative differential RX D-PHY input clock				
rx_d0_p_i	I	Positive differential RX D-PHY input data 0				
rx_d0_n_i	1	Negative differential RX D-PHY input data 0				
rx_d1_p_i	1	Positive differential RX D-PHY input data 1 (in case of 2-lane or 4-lane configuration)				
rx_d1_n_i	I	Negative differential RX D-PHY input data 1 (in case of 2-lane or 4-lane configuration)				
rx_d2_p_i	1	Positive differential RX D-PHY input data 2 (in case of 4-lane configuration)				
rx_d2_n_i	I	Negative differential RX D-PHY input data 2 (in case of 4-lane configuration)				
rx_d3_p_i	1	Positive differential RX D-PHY input data 3 (in case of 4-lane configuration)				
rx_d3_n_i	I	Negative differential RX D-PHY input data 3 (in case of 4-lane configuration)				
LVDS TX Inter	face					
tx0_clk_p_o	0	Positive differential TX LVDS output clock				
tx0_d0_p_o	0	Positive differential TX LVDS output data 0				
tx0_d1_p_o	0	Positive differential TX LVDS output data 1				
tx0_d2_p_o	0	Positive differential TX LVDS output data 2				
tx0_d3_p_o	0	Positive differential TX LVDS output data 3 (in case of TX_RGB888)				
tx1_clk_p_o	0	Positive differential TX LVDS output clock on 2 <sup>nd</sup> TX channel (in case of dual TX channel configuration)				
tx1_d0_p_o	0	Positive differential TX LVDS output data 0 on 2 <sup>nd</sup> TX channel (in case of dual TX channel configuration)				
tx1_d1_p_o	0	Positive differential TX LVDS output data 1 on 2 <sup>nd</sup> TX channel (in case of dual TX channel configuration)				
tx1_d2_p_o	0	Positive differential TX LVDS output data 2 on 2 <sup>nd</sup> TX channel (in case of dual TX channel configuration)				
tx1_d3_p_o	0	Positive differential TX LVDS output data 3 on 2 <sup>nd</sup> TX channel (in case of dual TX channel configuration with TX_RGB888)				

# 3. Design and Module Description

The top-level design (mipi2lvds.v) consists of the following modules:

- rx\_dphy
- byte2pix
- rgb2rgb (used only for CSI-2 RGB888)
- raw2rgb (used only for CSI-2 RAW8/RAW10/RAW12/RAW14)
- tx lvds
- int\_gpll
- i2c\_target (optional for CSI-2)
- int osc

The top-level design has a reset synchronization logic.

# 3.1. rx\_dphy

This module must be created for the RX channel according to channel conditions, such as the number of lanes, bandwidth, and others. Figure 3.1 and Figure 3.2 show an example of IP interface settings in Lattice Radiant for the CSI-2/DSI D-PHY Receiver Submodule IP. You can use the .ipx file (rx\_dphy/rx\_dphy.ipx) included in the sample project and reconfigure according to your needs. Refer to CSI-2/DSI D-PHY Receiver Submodule IP User Guide (FPGA-IPUG-02025) for details.

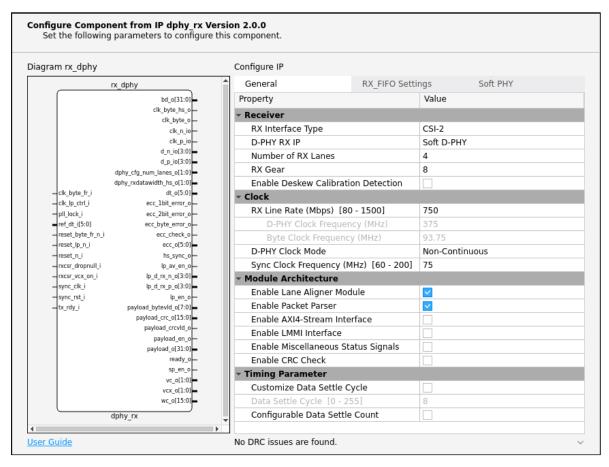

Figure 3.1. rx\_dphy IP Creation#1 in Lattice Radiant Software

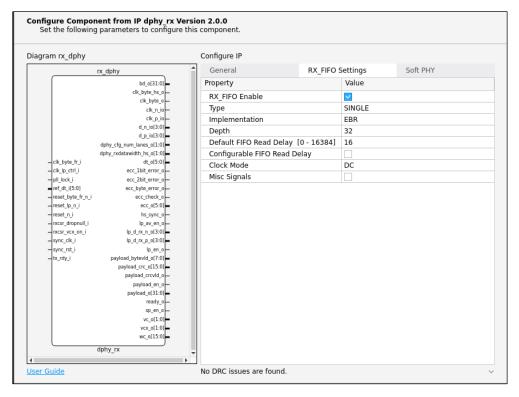

Figure 3.2. rx dphy IP Creation#2 in Lattice Radiant Software

The following provides the guidelines and parameter settings required for this reference design.

- RX Interface Select DSI or CSI-2.
- D-PHY RX IP The setting must match RX DPHY HARD setting.
- Number of D-PHY Data Lanes Set according to channel configuration. The value must match NUM\_RX\_LANE\_\*
  setting.
- RX Gear Select 8 or 16; 16 is recommended when the RX byte clock speed exceeds 100 MHz with Gear 8.
- CIL Bypass If RX\_DPHY\_HARD is defined, disable this option (unchecked).
- Enable LMMI Interface Select disabled (unchecked).
- Enable AXI4-Stream Interface Select disabled (unchecked).
- Enable Deskew Calibration Detection Select disabled (unchecked) for D-PHY input line rate below 1.5 Gbps.
- RX Line Rate Set according to channel configuration. 800 or below is recommended for 4 lane configuration.
- D-PHY Clock Mode Select Continuous or Non-continuous. Must match RX\*\_CLK\_MODE\_\* setting (Continuous = HS ONLY, Non-continuous = HS LP).
- Enable Packet Parser Select checkbox to enable (checked).
- Enable Miscellaneous Status Signals Select disabled (unchecked).
- Enable Lane Aligner Module Select checkbox to enable (checked) for Soft D-PHY with 2-lane and 4-lane configurations.
- RX\_FIFO Enable Select disabled (unchecked) for continuous clock mode with Soft D-PHY, select checkbox to enable (checked) for all other cases.
- Implementation Select EBR or LUT. Select LUT for continuous clock mode with Hardened D-PHY, refer to the RX FIFO section for non-continuous clock mode.
- Depth Select 16, 32, 64, 128, 256, 512, 1024, 2048 or 4096.
- Type Select SINGLE for continuous clock mode with Hardened D-PHY, refer to the RX FIFO section for noncontinuous clock mode.
- Packet Delay Set 1 for continuous clock mode with Hardened D-PHY, refer to the RX FIFO section for noncontinuous clock mode.
- Clock Mode Select DC (dual clock).
- Misc Signals Select disabled (unchecked).

14

This module takes serial CSI-2/DSI data and outputs byte data after de-serialization in MIPI High Speed mode. The .ipx file included in the project (rx\_dphy/rx\_dphy.ipx) can be used to reconfigure the IP according to the user configuration requirements. If you are creating this IP from scratch, it is recommended to set the design name to rx\_dphy so that you do not need to modify the instance names of these IPs in the top file as well as the simulation setup file. Otherwise, you need to modify the names accordingly.

#### 3.1.1. RX FIFO

RX FIFO is useful especially in non-continuous clock mode and the continuous byte clock cannot have the exact same frequency as the non-continuous byte clock used in D-PHY RX IP. It resides after the word aligner in case of Hardened D-PHY RX IP and resides before the word aligner in case of Soft D-PHY RX IP.

#### 3.1.1.1. Hardened D-PHY in Continuous Clock Mode

In this case, the minimum configuration of RX FIFO is recommended as mentioned above (LUT based, Depth = 16, type = SINGLE, Packet Delay = 1, Clock Mode = DC).

#### 3.1.1.2. Soft D-PHY in Continuous Clock Mode

In this case, RX FIFO is not necessary and RX FIFO Enable should be disabled (unchecked).

#### 3.1.1.3. Non-Continuous Clock Mode

In this case, RX FIFO configuration depends on the relationship between the non-continuous byte clock in D-PHY RX IP and the continuous byte clock, which is most likely generated by GPLL. The non-continuous byte clock is used to write the data to RX FIFO and the continuous byte clock is used to read the data from RX FIFO.

- Continuous byte clock = non-continuous byte clock
   In this case, the minimum configuration of RX FIFO is recommended (LUT based, Depth = 16, type = SINGLE, Packet Delay = 1, Clock Mode = DC). You can increase the Depth and Read Delay to absorb any PPM or phase differences between the clocks.
- Continuous byte clock < non-continuous byte clock
  In this case type = SINGLE and Packet Delay = 1 is recommended and others depend on the frequency ratio
  between these two clocks. When the clock speed difference gets larger, the required depth of RX FIFO gets larger.
  First, it is important to know the horizontal blanking period of the incoming RX channel. For example, in case that
  one-line active video period is 40 us and the horizontal blanking is 4 us, then we have 10 % of extra time to process
  the active data. This means the continuous byte clock can be as slow as ~-10% comparing to the non-continuous
  byte clock to avoid RX FIFO overflow.
- Continuous byte clock > non-continuous byte clock
   There are two options in this case:
  - Use type = SINGLE with large Packet Delay
     Set the Depth large enough to contain the necessary data to avoid RX FIFO underflow after FIFO read begins after the time specified by Packet Delay. In general, Packet Delay must be set close the depth of the RX FIFO. This configuration can be used when we have enough time interval between the last active line and the frame end short packet so that the frame end short packet is not written to RX FIFO while it still contains the last active line of video data.
  - Use type = QUEUE with Number of Queue Entries = 2
    This is useful when the time interval between the last active line and frame end short packet is short or unknown. Depth must be set large enough to contain one active line data (plus some more for short packet data). This mode is also useful when line start and the line end short packets exist in the incoming RX stream. In that case, Number of Queue Entries = 4 and extra depth is required (one line plus two short packet data). FIFO read begins after each HS data transaction is completed. EBR must be used. Counter Width is determined by the amount of the one-line video data plus extra overheads by preceding HS zero data and trail byte in the end of HS transmission.
  - Frequency relationship is unknown
     When the continuous byte clock is within the certain range against the non-continuous byte clock (for example, two clocks come from different clock sources which have ppm tolerance), we have no idea which

clock is faster. The simplest way is to use type = SINGLE with setting Packet Delay to the midpoint of FIFO depth when the tolerance is in ppm level. QUEUE can also be used as described above.

In case you do not have detailed information regarding RX data (whether containing lane start/end short packet, interval of the horizontal blanking period against active line period), the safest way is to set the continuous byte clock faster than the non-continuous byte clock and use type = QUEUE with Number of entries = 4 even though it might require more EBR resources comparing to type = SINGLE.

#### 3.2. byte2pix

This module must be created for the RX channel according to D-PHY type, data type, the number of lanes, RX Gear, and others. Figure 3.3 shows an example of IP interface settings in Lattice Radiant for the byte2pixel IP. You can use the byte2pix.ipx file (byte2pix/byte2pix.ipx) included in the sample project and reconfigure according to your needs. Refer to Byte-to-Pixel Converter IP User Guide (FPGA-IPUG-02027) for details.

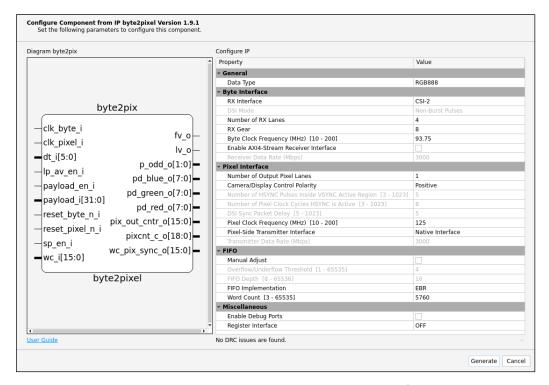

Figure 3.3. byte2pixel IP Creation in Lattice Radiant Software

The following provides the guidelines and parameter settings required for this reference design.

- RX Interface Select DSI or CSI-2. Set the same type as RX D-PHY IP.
- DSI Mode Select Non-Burst Pulses, Non-Burst Events or Burst (applicable to DSI Interface only)
- Number of RX Lanes Select 1, 2 or 4. Set the same value as RX D-PHY IP.
- RX Gear Select 8 or 16. Set the same value as RX D-PHY IP.
- Byte Side Clock Frequency Set the same value as is obtained in the RX D-PHY IP.
- Pixel Side Transmitter Interface Select Native Interface.
- Number of Output Pixels Lanes Select 1, 2 or 4.
- Data Type Select RGB888 for DSI and RGB888, RAW8, RAW10, RAW12, or RAW14 for CSI-2. Others are not supported in this reference design.
- Camera/Display Control Polarity Select Positive. Polarity setting of sync and data enable is done outside of this IP.
- Pixel Side Clock Frequency Enter the appropriate value (can be calculated from the mipi2lvds\_clock.xlsx).
- Pixel-Side Transmitter Interface Select Native Interface.
- Manual Adjust Select disabled (unchecked).
- Word Count Enter the appropriate value according to the following equation:
  - Word Count = (NUM PIXELS \* PD BUS WIDTH)/8
  - For example, in the case of 1080P with RAW10, the value is  $1920 \times 10/8 = 2400$ .
- Enable Debug Ports Select disabled (unchecked).

The Byte-to-Pixel Converter IP converts the D-PHY CSI-2/DSI standard based byte data stream to standard pixel data format. The .ipx file included in the project (byte2pix/byte2pix.ipx) can be used to reconfigure the IP according to the user configuration requirements. If you are creating this IP from scratch, it is recommended to set the design name to

All other brand or product names are trademarks or registered trademarks of their respective holders. The specifications and information herein are subject to change without notice.

17

byte2pix so that you do not need to modify the instance name of this IP in the top-level design as well as in the simulation setup file. Otherwise, you need to modify the names accordingly.

This module receives byte data from RX D-PHY along with packet enable signal, among others, and reorganizes the data to form the desired pixel data via FIFO according to the data type specified. FIFO is used as a data buffer as well as clock domain conversion. Byte data are written to FIFO in byte clock domain and read in pixel clock domain. Pixel clock is provided from TX LVDS module.

Depending on the D-PHY type (DSI or CSI-2), different types of sync and data enable signals are generated. Figure 3.4 shows the interface timing diagram for DSI. VSYNC, HSYNC, and DE are generated based on short packet enable and payload enable signals. In case of DSI, these signals are sent to LVDS TX module as is. Depending on the configuration, output data (pd\_o) could have one, two, or four pixels per pixel clock. Figure 3.5 shows global output timing for DSI. Due to the clock domain crossing, the pulse length and/or sync signal intervals may vary slightly.

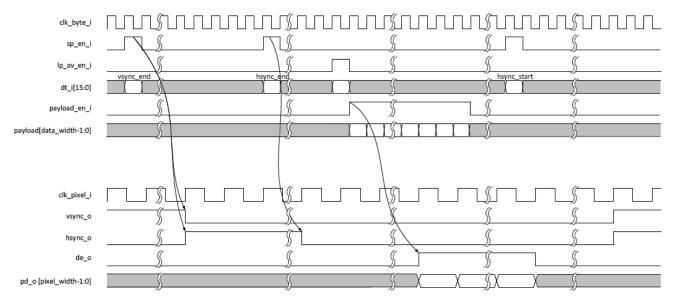

Figure 3.4. Interface Timing Diagram for DSI

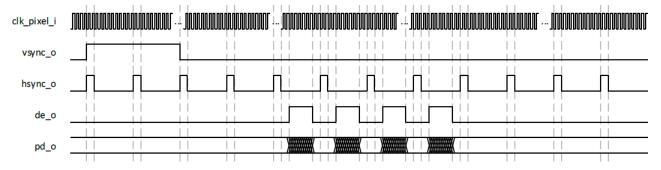

Figure 3.5. Global Output Timing Diagram for DSI

Figure 3.6 shows the interface timing diagram for CSI-2. FV and LV are generated based on short packet enable and payload enable signals. Figure 3.7 shows global output timing for CSI-2. In case of CSI-2, sync signals (VSYNC, HSYNC) have to be created from FV and LV to match the interface format of LVDS. Also in case of RAW8/RAW10/RAW12/RAW14, RGB pixel data have to be created from RAW data. For these purposes, an additional module (rgb2rgb or raw2rgb) is required for CSI-2 between byte2pixel and tx\_lvds. In case of two TX channel outputs, output data (pd\_o) has two pixels per pixel clock.

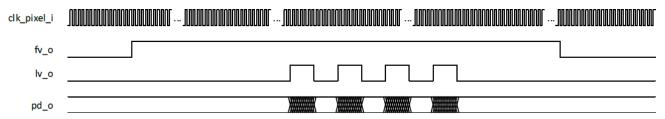

Figure 3.7. Global Output Timing Diagram for CSI-2

# 3.3. rgb2rgb

This module is instantiated for CSI-2 RX with RGB888 and has two major functions: sync signal generation and video data trimming.

#### 3.3.1. Sync Signal Generation

Since sync signal format is different between CSI-2 and LVDS, VSYNC and HSYNC signals have to be created from FV and LV comes from byte2pix. For that purpose, the following parameters are prepared:

- HFP (Horizontal Front Porch)
- HS LENGTH (Horizontal Sync Length)
- VFP (Vertical Front Porch)
- VS LENGTH (Vertical Sync Length)

The above parameter values can be changed through register writes when USE\_I2C is defined. Otherwise, the values specified in synthesis\_directives.v are applied. Note that (HFP + HS\_LENGTH) must be shorter than the horizontal blanking period. Otherwise, HSYNC active period and DE active period overlap and we cannot expect the anticipated image on the display.

If you don't know the length of the horizontal blanking period, a small value should be set. For example, HFP = 2, HS\_LENGTH = 2, and others, as long as the display accepts it. In addition, (VFP + VS\_LENGTH) must be smaller than the vertical blanking period for the same reason. HFP and VFP counts begin at the end of non- trimmed active pixel and active line. That means the actual blanking periods are larger than HPF or VFP if trimming happens on the right edge or bottom edge.

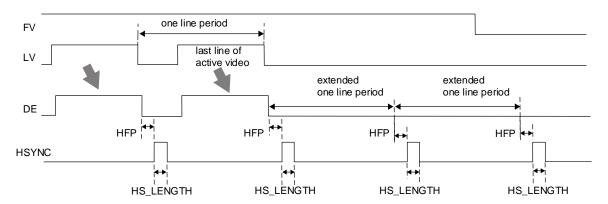

Figure 3.8. HSYNC Generation

During the vertical blanking period, HSYNC is generated by extending the line interval obtained by LV falling edges during the active line period as shown in Figure 3.8. One potential problem, however, is that HSYNC assertion could happen when the first DE of the next frame comes since there is no guarantee that the length of the vertical blanking period is multiple of one horizontal line period. To avoid this situation, a shift register is provided. FV/LV and payload data are all written to the shift register FIFO and comes out after the specified pixel clock cycle delay set by the parameter SR\_DELAY. Figure 3.9 shows the masking of HSYNC which overlaps DE period. If the display has the minimum requirement of HBP (Horizontal Blanking Period: period from the end of HSYNC to the beginning of DE), SR\_DELAY value should satisfy the following equation:

$$SR\_DELAY > HS\_LENGTH + minimum HBP$$

VSYNC/HSYNC assertions are controlled based on these delayed signals, but HSYNC assertion is disabled when the original LV is active. By changing this parameter value, you can change the HSYNC mask period. This parameter can also be changed through register write when USE I2C is defined.

All other brand or product names are trademarks or registered trademarks of their respective holders. The specifications and information herein are subject to change without notice.

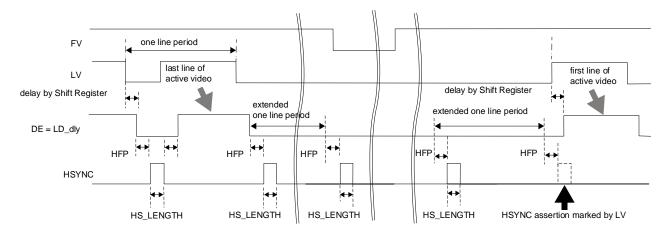

Figure 3.9. HSYNC Masked by LV

Since VSYNC generation is based on the assertion timing of HSYNC, and HSYNC assertion is based on the falling edge of LV, VSYNC of the current outgoing frame requires the previous incoming video timings. Therefore, no VSYNC assertion happens for the first incoming video frame and DE is masked for that frame. Valid VSYNC and video data outputs begin from the second incoming frame.

#### 3.3.2. Active Data Trimming

In some cases, video data from sensor devices have an area that is larger than what is required by the display. For this reason, edge trimming capability is provided using following parameters:

- LEFT\_TRIM (trimming pixels from the left edge)
- H TX PEL (active pixel count)
- TOP\_TRIM (trimming lines from the top edge)
- V\_TX\_LINE (active line count)

The above parameter values can be changed through register write when USE\_I2C is defined. Otherwise, the values specified in synthesis\_directives.v are applied. Note that (LEFT\_TRIM + H\_TX\_PEL) must not exceed the original horizontal active pixel count, otherwise output image is corrupted. In addition, (TOP\_TRIM + V\_TX\_LINE) must not exceed the original active line count for the same reason.

## 3.4. raw2rgb

This module is instantiated for CSI-2 RX with RAW8/RAW10/RAW12/RAW14 and has three major functions: RGB data creation, sync signal generation and video data trimming.

#### 3.4.1. RGB Data Creation

In the case of RAW data format, one pixel contains only one color component of RGB. Therefore, missing color components must be created by interpolation to form RGB888. Figure 3.10 shows four scenarios of Bayer patterns of the color components at the top-left pixels come from the image sensor.

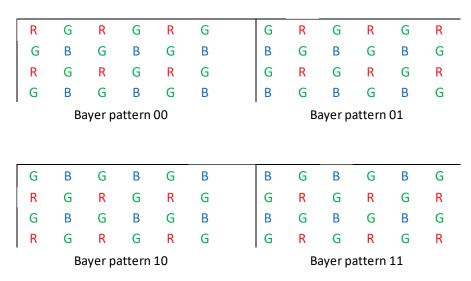

Figure 3.10. Bayer Pattern of RAW Data

Missing color components are created by interpolation using the neighborhood pixels. Figure 3.11 shows examples of interpolations to create all three color components for the center pixel. Either 2-pixel averaging or 4-pixel averaging is applied, depending on the location of the pixel, to create the missing color components.

```
В
               В
                         R(interpolated) = R(center)
       G
               G
                         G(interpolated) = (G(top) + G(bottom) + G(left) + G(right)) / 4
G
В
               В
                         B(interpolated) = (B(top-left) + B(top-right) + G(bottom-left) + G(bottom-right)) / 4
G
               G
                          R(interpolated) = (R(left) + R(right)) / 2
R
               R
                         G(interpolated) = G(center)
                          B(interpolated) = (B(top) + B(bottom)) / 2
G
       В
               G
```

Figure 3.11. RGB Data Creation from RAW Data

Due to the necessity of vertical interpolation, this module has two line buffers with the depth specified by the directive LB\_DEPTH\_\*. In case of edge and corner pixel interpolations (top line, bottom line, left edge, right edge), mirroring is applied to cover the non-existing pixels. For example, there are no top pixels for the first line pixel interpolation and the bottom (second line) pixels are used instead of the non-existing top pixels. Same method applies to left edge, right edge, and bottom line pixel interpolations. Note that the first line output is roughly aligned with the second incoming line due to the line buffering delay.

22

#### 3.4.2. Sync Signal Generation

Scheme is same as CSI-2 RGB888 input except for the non-existence of the shift register. In case of RAW data processing, a single line process delay happens due to the line buffer mentioned in the RGB Data Creation section, the HSYNC masking feature is not required using the shift register.

#### 3.4.3. Active Data Trimming

Scheme is same as CSI-2 RGB888 input.

## 3.5. tx\_lvds

You must create this module according to channel conditions, such as number of lanes, bandwidth, and others. Figure 3.12 shows an example IP interface setting in Lattice Radiant for the OpenLDI/LVDS Transmitter Interface IP. You can use the ipx file (tx\_lvds/tx\_lvds.ipx) included in the sample project and re-configure according to your needs. Refer to OpenLDI/FPD-LINK/LVDS Transmitter Interface IP User Guide (FPGA-IPUG-02022) for details.

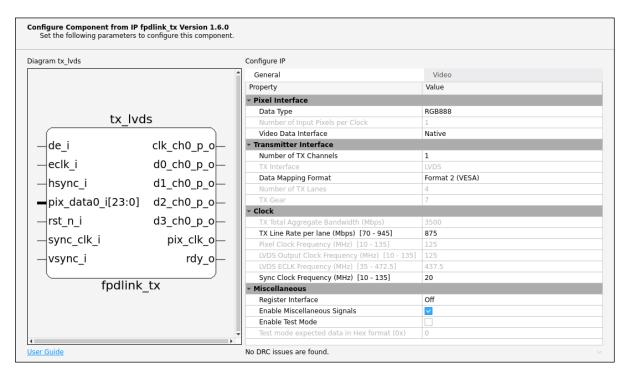

Figure 3.12. tx\_dphy IP Creation in Lattice Radiant Software

The following provides the guidelines and parameter settings required for this reference design.

- Number of TX Channels Set according to channel configuration. Must match NUM\_TX\_CH\_\* setting. Refer to Table 1.1 for possible TX channel setting.
- Data Mapping Format Select the suitable format. Note that the simulation supports only Format 2 (VESA).
- Data Type select RGB888.
- TX Line Rate Set the value derived from the TX Lane Bandwidth equation below.
- Sync Clock Frequency Select the value, which is equal to or lower than the slowest clock in the system
- Enable miscellaneous status signals Must be enabled (checked).
- Enable test mode Must be disabled (unchecked).

This module takes the pixel data and outputs LVDS data after 7:1 serialization. If you are creating this IP from scratch, it is recommended to set the design name to tx\_lvds and module name to tx\_lvds so that you do not need to modify the instance name of this IP in the top level design as well as simulation setup file. Otherwise, you need to modify the names accordingly.

All other brand or product names are trademarks or registered trademarks of their respective holders. The specifications and information herein are subject to change without notice.

© 2025 Lattice Semiconductor Corp. All Lattice trademarks, registered trademarks, patents, and disclaimers are as listed at www.latticesemi.com/legal

TX Line Rate is derived from the following equation:

$$TX\_lane\_bandwith = \frac{RX\_lane\_bandwidth*number\_of\_RX\_lane*7}{RX\_pixel\_bus\_width*number\_of\_TX\_channel}$$

Example 1: CSI-2 RAW10 RX with 4-lane at RX lane bandwidth = 200 Mbps TX lane bandwidth =  $(200 \times 4 \times 7) / (10 \times 1) = 560$  Mbps.

Example 2: DSI RGB888 RX with 4-lane at RX lane bandwidth = 1200 Mbps with dual channel TX outputs TX lane bandwidth =  $(1200 \times 4 \times 7) / (24 \times 2) = 700 \text{ Mbps}$ .

Figure 3.13 and Figure 3.14 show the output data timings of single and dual channel configuration with RGB888. RGB888 uses four data lanes per channel.

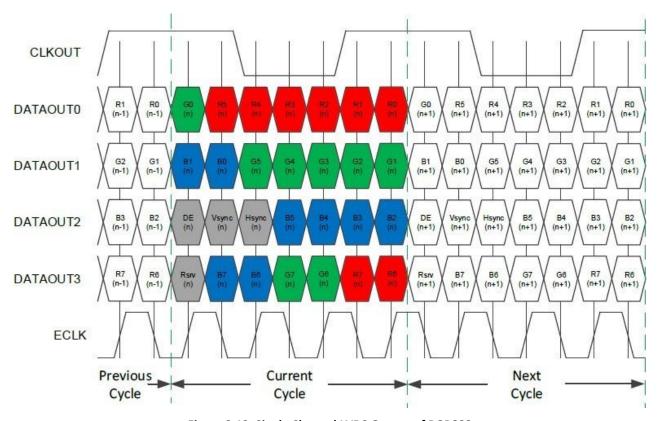

Figure 3.13. Single Channel LVDS Output of RGB888

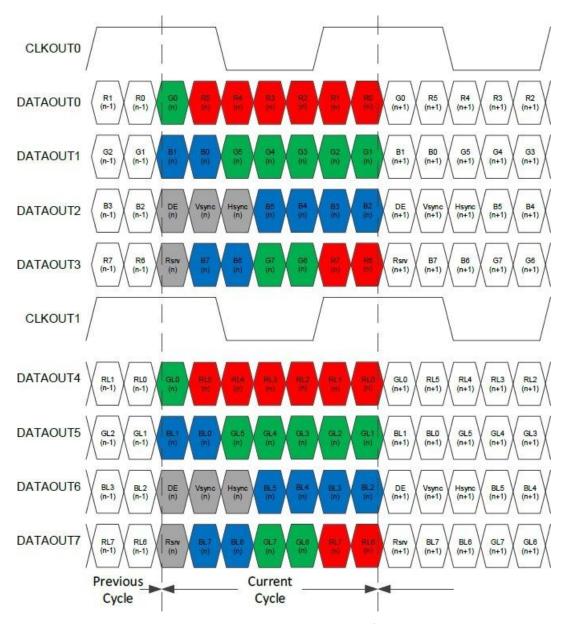

Figure 3.14. Dual Channel LVDS Output of RGB888

# 3.6. int\_gpll

You must create GPLL module to feed the edge clock to tx\_lvds. Additionally, the continuous byte clock could be generated when RX D-PHY is in HS\_LP mode. You can use the ipx file (int\_gpll/int\_gpll.ipx) included in the sample project and re-configure according to your needs. In case that you make this IP from scratch, it is recommended to set the design name to <code>int\_gpll</code> so that you do not need to modify the instance name of this IP in the top level design as well as simulation setup file. Otherwise, you need to modify the names accordingly.

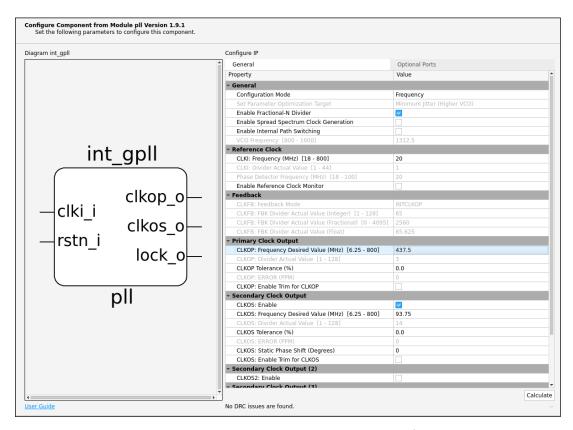

Figure 3.15. GPLL IP Creation#1 in Lattice Radiant Software

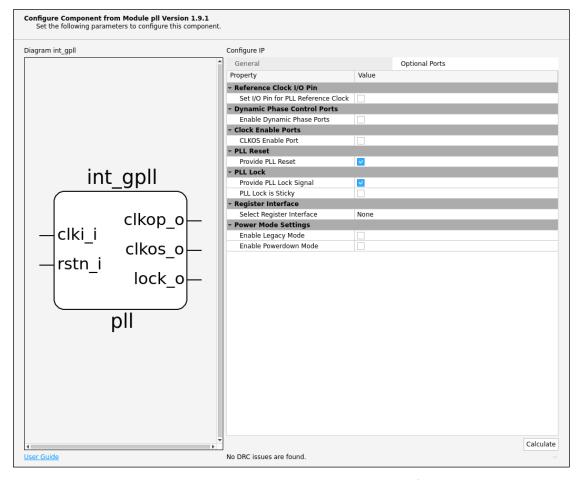

Figure 3.16. GPLL IP Creation#2 in Lattice Radiant Software

The TX edge clock frequency is half of the TX lane bandwidth set for tx\_lvds. This clock must be assigned to CLKOP. If the byte clock has to be generated, assign it to CLKOS. Note that the VCO clock of GPLL has to be a common multiple of these two clocks. There is a case wherein TX edge clock and byte clock cannot be generated together. In this instance, give up generating the byte clock by GPLL and perform either of the following options:

- Change RX D-PHY to HS\_ONLY mode; or
- Feed the continuous byte clock directly from one of the available I/O pins.

If the RX D-PHY is in HS\_ONLY mode and GPLL can generate the TX edge clock using the byte clock as the input clock of GPLL (CLKI), the external reference clock is not necessary. int\_gpll instantiation based on the configuration is shown below as a code snippet of mipi2lvds.v:

```
//// GPLL instantiation
                                                  11111
//// User has to modify this if necessary
                                                  /////
`ifdef EXT_REF_CLK
`ifdef RX_CLK_MODE_HS_LP
    int_gpll pll_inst (
        .CLKI (ref_clk_i), // ref clock
        .CLKOP(pll_eclk),
                         // tx edge clock
            .CLKOS(pll_byte_clk),
                            // byte clock
            .LOCK (pll lock)
        );
```

© 2025 Lattice Semiconductor Corp. All Lattice trademarks, registered trademarks, patents, and disclaimers are as listed at www.latticesemi.com/legal.

All other brand or product names are trademarks or registered trademarks of their respective holders. The specifications and information herein are subject to change without notice.

If you can use ref\_clk\_i (or simply divided clock of this) as byte\_clk in HS\_LP mode, you should disable CLKOS and add the following in mipi2lvds.v:

```
assign pll_byte_clk = ref_clk_i; // ref_clk_i could be simply divided clock of this
```

More than one GPLL can be used if the required clock frequencies for the rx\_clk\_byte\_fr and pll\_eclk cannot be generated using a single GPLL as shown below:

```
`ifdef EXT REF CLK
`ifdef RX CLK MODE HS LP
      int_gpll pll_inst (
             .rstn i
                          (reset n i),
                                             // ref clock
             .clki i
                          (ref_clk_i),
                                           // tx edge clock
             .clkop o
                          (pll_byte_clk),
                    .lock_o
                                (pll_lock_i)
                   );
             int_gpll_2 pll_inst_2 (
                    .rstn i
                                (reset_n_i),
                                                    // ref clock
                    .clki_i
                                 (ref_clk_i),
                                 (pll_eclk),
                                                    //tx edge clock
                    .clkop_o
                    .lock o
                                (pll_lock_2)
                   );
```

# 3.7. i2c\_target

This module is instantiated when USE\_I2C is defined and enables you to change CSI-2 related parameters on the fly through I2C connections. I2C Hardened IP is instantiated and used as an I2C target device. You can use the .ipx file (i2c\_s/i2c\_s.ipx) included in the sample project and re-configure. In case that you create this IP from scratch, it is recommended to set the design name to i2c\_s so that you do not need to modify the instance name of this IP in the top level design as well as simulation setup file. Otherwise, you need to modify the names accordingly.

Figure 3.17 shows basic settings of I2C IP. You can change the settings according to your design's needs.

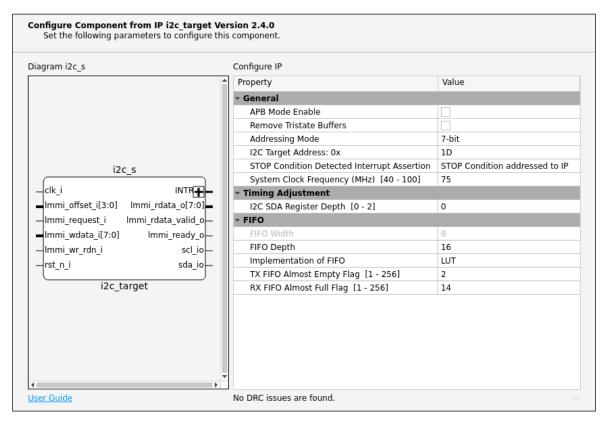

Figure 3.17. I2C IP Creation in Lattice Radiant Software

This module is equipped with parameter registers of 4-bit address area of I2C sub address shown in Table 3.1.

Table 3.1. I2C Target Register Map

Sub Address	Name	Bits	Description	
0	SW Reset	[0]	Software reset register. When this is active, all modules except for i2c_target are in reset condition. Active low.	
1	SR Delay	[7:0]	Shift Register delay register. Sync and data from byte2pixel are delayed before processed in rgb2rgb. The value must be 8'd2 – 8'd255.	
2	Bayer Pattern	[1:0]	Bayer Pattern register. The value must be 2'00, 2'b01, 2'b10, or 2'b11.	
3	HFP	[7:0]	Horizontal Front Porch register. The value must be 8'd1 – 8'd255.	
4	HS_LENGTH	[7:0]	HSYNC Length register. The value must be 8'd1 – 8'd255.	
5	VFP	[5:0]	Vertical Front Porch register. The value must be 6'd1 – 6'd63.	
6	VS_LENGTH	[5:0]	VSYNC Length register. The value must be 6'd1 – 6'd63.	
7	LEFT_TRIM	[5:0]	Left Edge Trim register. The value must be 6'd0 – 6'd63.	
8	H_TX_PEL_LSB	[7:0]	Horizontal Active Pixel register. The value must be 12'd1 – 12'd4095.	
9	H_TX_PEL_MSB	[11:8]		
10	TOP_TRIM	[5:0]	Top Edge Trim register. The value must be 6'd0 – 6'd63.	
11	V_TX_LINE_LSB	[7:0]	Vertical Active Line register. The value must be 12'd1 – 12'd4095.	
12	V_TX_LINE_MSB	[11:8]	7	
13	_	N/A	Reserved	
14	_	N/A	Reserved	
15	_	N/A	Reserved	

#### Notes:

- 1. All registers less than 8-bit data width are aligned to LSB of 8-bit data area.
- 2. All registers are set to the default values specified by corresponding directives defined in synthesis\_directives.v
- 3. Software reset works as the system reset (reset\_n\_i) for all modules other than i2c\_target, therefore you can assert this while updating other I2C registers, then release Software reset upon completing the register update to avoid an unexpected operation during register update. Refer to the rgb2rgb and raw2rgb sections for register details.

# 3.8. int\_osc

This module is instantiated when the i2c\_target module is enabled in the design. It is used to generate a 75 MHz clock for the i2c\_target module. It can also be used to provide clocks to RX D-PHY IP (sync\_clk\_i, clk\_lp\_ctrl\_i, etc.) when the frequency of the clocks from other sources available in the design is not matching the requirements. You can use the ipx file (int\_osc/int\_osc.ipx) included in the sample project and re-configure according to your needs. In case you generate this IP from scratch, it is recommended to set the module name to int\_osc so that you do not need to modify the instance name of this IP in the top level design as well as simulation setup file. Otherwise, you need to modify the names accordingly. Figure 3.18 shows an example of IP interface settings in Lattice Radiant software for the int\_osc IP.

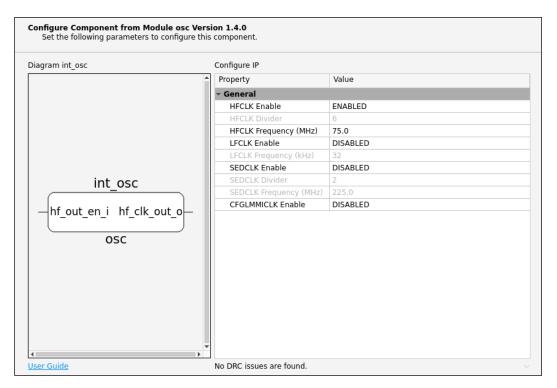

Figure 3.18. int\_osc IP Creation in Lattice Radiant Software

# 4. Design and File Modification

This RD is based on RX D-PHY IP v2.0.0, Byte-to-Pixel Converter IP v1.9.1, and OpenLDI/LVDS Transmitter Interface IP v1.6.0. Due to the limitation of these IPs, some modifications are required depending on user configuration in addition to two directive files (synthesis directives.v, simulation directives.v).

## 4.1. Top Level RTL

If you use I2C target module or RX D-PHY IP with a clock other than the internal oscillator clock, you will have to disable the int\_osc (internal oscillator) instantiation and connect an appropriate clock to clk\_i port of i2c\_target, sync\_clk\_i port of Soft RX D-PHY IP and clk\_lp\_ctrl\_i port of RX D-PHY IP in non-continuous clock mode.

In case of HS\_LP mode and the external reference clock can be used as byte\_clk without using GPLL, you have to modify the related code as described in the int\_gpll section. In addition, instance names of RX D-PHY, Byte-to-Pixel, TX LVDS IP have to be modified if you created these IP with different names.

# 5. Design Simulation

The script file (sim/mipi2lvds\_msim.do) and testbench files are provided to run the functional simulation by QuestaSim. If you keep the current design names and instance names when RX D-PHY, Byte-to-Pixel, TX LVDS, GPLL, and I2C IPs are created in the Lattice Radiant software, you can follow the steps to run the simulation as follows:

- 1. Launch QuestaSim using the Lattice Radiant software.
- 2. Execute the following command in the QuestaSim terminal:

```
cd sim
source mipi2lvds_msim.do
```

You need to modify simulation\_directives.v according to your configuration (refer to the Simulation Directives section for details). By executing the script in QuestaSim, compilation and simulation are executed automatically. The testbench takes all data comparison between the expected data and output data from the RD. Note that data comparison begins from the second input frame in case of CSI-2 input due to VSYNC signal creation delay. It shows following statements while running and doing data comparison:

```
# Frame 1, Line
                  0, Pixel
                              0 CHO Active Data: R = 83, G = 7a, B = 19 matched
  297690312 DPHY Driving Data
 297690312 DPHY Lane 0 : Driving with data = 2e
 297695312 DPHY Driving Data
  297695312 DPHY Lane 0 : Driving with data = 26
# Frame 1, Line
                  0, Pixel
                               1 CHO Active Data : R = 4a, G = ef, B = 19 matched
  297700312 DPHY Driving Data
 297700312 DPHY Lane 0 : Driving with data = 8c
# Frame 1, Line
                  0, Pixel
                               2 CHO Active Data : R = 10, G = d3, B = 22 matched
  297705312 DPHY Driving Data
 297705312 DPHY Lane 0 : Driving with data = 0d
  297710312 DPHY Driving Data
 297710312 DPHY Lane 0 : Driving with data = 77
# Frame 1, Line
                  0, Pixel
                               3 CHO Active Data: R = 37, G = c9, B = 2b matched
  297715312 DPHY Driving Data
 297715312 DPHY Lane 0 : Driving with data = a8
# Frame 1, Line
                  0, Pixel
                              4 CHO Active Data : R = 5e, G = b8, B = 5d matched
  297720312 DPHY Driving Data
  297720312 DPHY Lane 0 : Driving with data = a7
```

Data comparison is based on the detection of the DE assertion after the deserialization by the testbench. Simulation stops when the data comparison failure happens.

Also, you should find the following statements during the vertical blanking periods since there is no DE assertion:

```
##### tx0 DE de-assertion #####
##### tx0 HSYNC assertion ####
##### tx0 HSYNC de-assertion ####
##### tx0 HSYNC assertion ####
##### tx0 HSYNC de-assertion ####
##### tx0 VSYNC assertion ####
##### tx0 HSYNC assertion ####
##### tx0 HSYNC de-assertion ####
##### tx0 VSYNC de-assertion ####
```

When the simulation is finished, the following statements are displayed (example of CSI-2):

```
##### tx0 HSYNC assertion #####
##### tx0 HSYNC de-assertion #####
# 806980625 DPHY CSI-2 after frame gap
#
# Total pixels checked were 19200 = 2 Frames x 1920 x pels x 5 lines : all matched !!!!!
# Simulation Succeeded !!!!!
# 812080625 TEST END
```

The above is the result after running three frames. In case of CSI-2, DE is not asserted in the first frame and data comparison occurs in the second frame and after.

Figure 5.1 shows the global timing of DSI RGB888 with single channel LVDS output. In the case of DSI, all signals are passed through and de-serialized LVDS signals (tx0\_des\_\*) by the de-serializer model in the testbench shows the same behavior as rx\_dphy outputs (rx\_vsync/hsync/de) and tx\_lvds inputs (tx\_vsync/hsync/de). In this case, LP period exists before VSYNC.

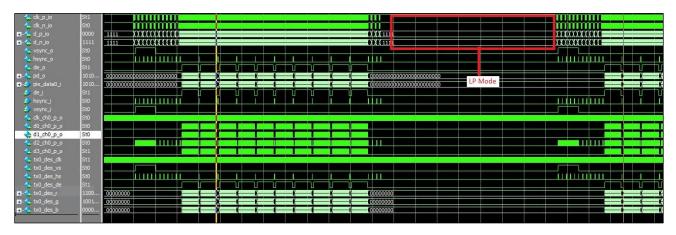

Figure 5.1. Global Timing of DSI RGB888 without Vertical Trimming

Figure 5.2 shows the global timing of CSI-2 RGB888 without vertical trimming. HSYNC is created during the LP mode period between two frames. In this simulation, VFP = 2 and VS LENGTH = 2 are set.

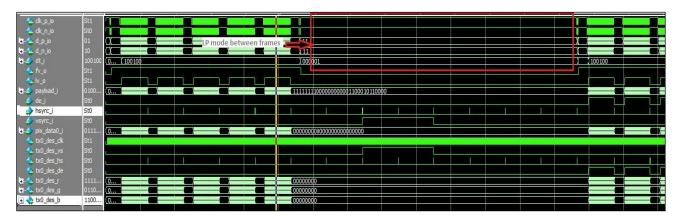

Figure 5.2. Global Timing of CSI-2 RGB888

Figure 5.3 shows the global timing of CSI-2 RAW10 without vertical trimming. DE assertion begins from the second frame after VSYNC creation with VFP = 2 and VS\_LENGTH = 2. Due to RAW to RGB conversion, there exists one-line delay between RX data and TX data.

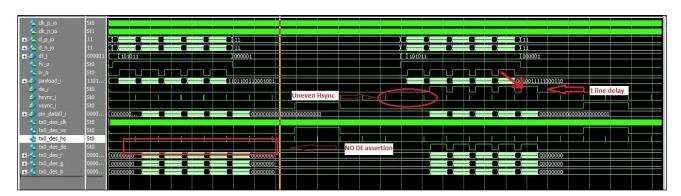

Figure 5.3. Global Timing of CSI-2 RAW10 without Vertical Trimming

Figure 5.4 shows the global timing of CSI-2 RAW10 with vertical trimming with VFP = 2 and VS\_LENGTH = 2. The first line and last line are trimmed. The actual VFP is 3 due to the trimming. Before the first frame data are fed, parameter update happens through I2C while software reset (int\_rst\_n) is asserted. Upon the completion of parameter update, the reset is released and the first frame data input begins.

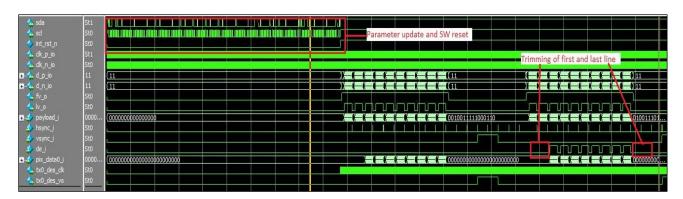

Figure 5.4. Global Timing of CSI-2 RAW10 with Vertical Trimming

# 6. Known Limitations

The following are the limitation of this reference design:

- Only following data types are supported for MIPI DSI input interface: RGB888.
- Only following data types are supported for MIPI CSI-2 input interface: RGB888, RAW8, RAW10, RAW12, RAW14.
- Only RGB888 is supported for the LVDS outputs.
- Simulation checkers only supports Data Mapping Format Type 2 (VESA).

# 7. Design Package and Project Setup

Figure 7.1 shows the directory structure. synthesis\_directives.v and simulation\_directives.v are set to configure an example shown below:

- RX: RGB888 four lanes with Soft D-PHY, Gear 8 in non-continuous clock mode
- TX: RGB888 four lanes with Gear 7

You can modify the directives for own configuration.

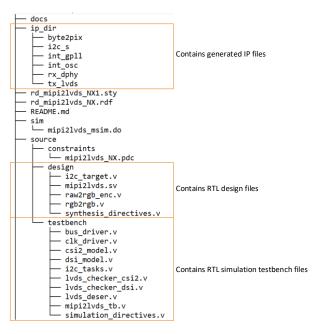

Figure 7.1. Directory Structure

Folders byte2pix, i2c\_s, int\_gpll, rx\_dphy, int\_osc, and tx\_lvds are created by Lattice Radiant for corresponding IPs.

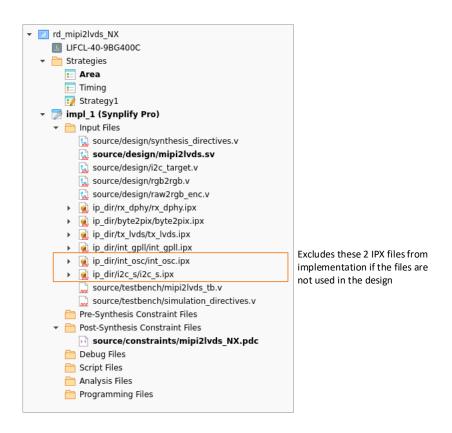

Figure 7.2. Project Files

Figure 7.2 shows design files used in the Lattice Radiant project. Lattice Radiant creates six .ipx files. By specifying mipi2lvds as a top-level design, all unnecessary files are ignored.

# 8. Resource Utilization

Resource utilization depends on the configurations. Table 8.1 shows resource utilization examples under certain configurations targeting LIFCL-40. LB depth is 4096 in case of CSI-2 RAW8/10/12/14. This is just a reference and actual usage may vary.

**Table 8.1. Resource Utilization Examples** 

Configuration	LUT4 (Utilization/Total)	FF (Utilization/Total)	EBR (Utilization/Total)	1/0
CSI2 RGB888 Soft D-PHY RX channel with 4 lanes, non-continuous clock mode, Gear 8 to single TX channel with Gear 7	1973/32256	1616/32811	8/84	19
CSI2 RAW Hard D-PHY RX channel with 4 lanes, continuous clock mode, Gear 8 to single TX channel with Gear 7	1853/32256	1542/32256	8/185	8

# **Revision History**

## Revision 1.1, July 2025

Section	Change Summary			
All	<ul> <li>Renamed document from MIPI DSI/CSI-2 to OpenLDI LVDS Interface Bridge for Crosslink-NX to MIPI DSI/CSI-2 to OpenLDI LVDS Interface Bridge for CrossLink-NX Devices.</li> <li>Changed instances of Master to Controller and Slave to Target.</li> <li>Replaced I<sup>2</sup>C with I2C.</li> <li>Performed minor formatting and editorial edits.</li> </ul>			
Disclaimers	Updated disclaimers.			
Inclusive Language	Added inclusive language boilerplate.			
Acronyms in This Document	Added definition for I2C.			
Introduction	<ul> <li>Added the link to the reference design in the Introduction section.</li> <li>Added RAW14 data type in the Features section.</li> <li>Added RAW14 data type in Table 1.1. RX and TX Permutation.</li> </ul>			
Parameters and Port List	<ul> <li>Updated Table 2.1 Synthesis Directives as follows:</li> <li>Added support for RAW14 for RX Data Type, Line Buffer Depth, and Bayer Pattern.</li> <li>Removed note on LSB two bits of I2C target address.</li> <li>Updated support for RAW14 for Bayer Pattern in Table 2.2. Simulation Directives.</li> </ul>			
Design and Module Description	<ul> <li>Added RAW14 for raw2rgb modules in the Design and Module Description section.</li> <li>Updated the rx_dphy section as follows:</li> <li>Updated Figure 3.1. rx_dphy IP Creation#1 in Lattice Radiant Software and Figure 3.2. rx_dphy IP Creation#2 in Lattice Radiant Software.</li> <li>Updated the description for CIL Bypass, Enable Deskew Calibration Detection, and Depth parameters.</li> <li>Updated the description for continuous byte clock in the Non-Continuous Clock Mode section.</li> <li>Updated the byte2pix section as follows: <ul> <li>Updated Figure 3.3. byte2pixel IP Creation in Lattice Radiant Software.</li> <li>Removed the Enable AXI4-Stream Slave Interface and Enable AXI4-Stream Master Interface parameters.</li> <li>Added the Pixel Side Transmitter Interface and Pixel-Side Transmitter Interface parameters.</li> <li>Added support for RAW14 data type.</li> <li>Updated the raw2rgb section as follows: <ul> <li>Added support for RAW14 data type.</li> <li>Updated the Xync Signal Generation and Active Data Trimming sections.</li> </ul> </li> <li>Updated Figure 3.12. tx_dphy IP Creation in Lattice Radiant Software.</li> <li>Added description for the Data Mapping Format parameter.</li> <li>Updated Figure 3.15. GPLL IP Creation#1 in Lattice Radiant Software and Figure 3.16. GPLL IP Creation#2 in Lattice Radiant Software in the int_gpll section.</li> <li>Updated Figure 3.17. I2C IP Creation in Lattice Radiant Software in the i2c_target section.</li> <li>Updated Figure 3.18. int_osc IP Creation in Lattice Radiant Software in the int_osc section.</li> </ul> </li> </ul>			
Design and File Modification	Updated IP versions in the Design and File Modification section.			
Design Simulation	<ul> <li>Updated the script file path.</li> <li>Changed ModelSim to QuestaSim.</li> <li>Updated the steps to run the simulation.</li> </ul>			

Section	Change Summary
	Removed the following figures:
	Script File Modification
	Script File Modification #2
Known Limitations	Added RAW14 data type support for MIPI CSI-2 input interface.
	Added limitations on the simulation checkers data mapping format support.
	Removed limitations on the Byte2Pix IP.
Design Package and ProjectSetup	Updated the configuration example for RX and TX.
	<ul> <li>Updated the design files and folders of the reference design.</li> </ul>
	Updated the following figures:
	Figure 7.1. Directory Structure
	Figure 7.2. Project Files
Resource Utilization	Updated section.
References	Updated references.
Technical Support Assistance	Added link to the Lattice Answer Database.

#### Revision 1.0, February 2021

Section	Change Summary
All	Initial release.
